WIRELESS COMPUTING DEVICE AND METHOD THEREFORE

BACKGROUND

Wireless communication systems are often regulated by governing agencies (e.g.

5 state or national governments) to reduce the risk that one communication system interferes with another. Regulations are typically implemented through cellular standards that define the conditions under which transmissions made be made. For example, a standard may describe how a base station or a cellular phone may transmit a message. Consequently, the standards strongly tie together the operation of the components of a
10 cellular system and provide little, if any, flexibility in how the components of the system may operate.

To further reduce the risk of interference between communication systems, governing agencies often require that a wireless product be thoroughly tested before it may be permitted to be used in a particular market. Such testing is referred to as type approval and is intended to determine if a particular wireless product operates properly within the standard and not interfere with other wireless communications. However, if even the slightest of modifications is made with a new model of a product (e.g., a new feature or form factor), the new product usually has to go through the entire type approval process.

20 Consequently, the standards used to govern wireless communications system make it difficult for third parties to develop new applications or add new features to wireless computing or communication devices. Thus, there is a continuing need for ways to allow applications and features to be added to wireless devices.

BRIEF DESCRIPTION OF THE DRAWINGS

The subject matter regarded as the invention is particularly pointed out and distinctly claimed in the concluding portion of the specification. The invention, however, both as to organization and method of operation, together with objects, features, and 5 advantages thereof, may best be understood by reference to the following detailed description when read with the accompanying drawings in which:

FIG. 1 is a block diagram representation of an embodiment of a portable device in accordance with an embodiment of the present invention; and

FIG. 2 is a module diagram representing the relationship between programs executed on a portable device in accordance with an embodiment of the present 10 invention.

It will be appreciated that for simplicity and clarity of illustration, elements illustrated in the figures have not necessarily been drawn to scale. For example, the 15 dimensions of some of the elements are exaggerated relative to other elements for clarity. Further, where considered appropriate, reference numerals have been repeated among the figures to indicate corresponding or analogous elements.

DETAILED DESCRIPTION

20 In the following detailed description, numerous specific details are set forth in order to provide a thorough understanding of the invention. However, it will be understood by those skilled in the art that the present invention may be practiced without these specific

details. In other instances, well-known methods, procedures, components and circuits have not been described in detail so as not to obscure the present invention.

Some portions of the detailed description which follow are presented in terms of algorithms and symbolic representations of operations on data bits or binary digital signals 5 within a computer memory. These algorithmic descriptions and representations may be the techniques used by those skilled in the data processing arts to convey the substance of their work to others skilled in the art.

An algorithm is here, and generally, considered to be a self-consistent sequence of acts or operations leading to a desired result. These include physical manipulations of 10 physical quantities. Usually, though not necessarily, these quantities take the form of electrical or magnetic signals capable of being stored, transferred, combined, compared, and otherwise manipulated. It has proven convenient at times, principally for reasons of common usage, to refer to these signals as bits, values, elements, symbols, characters, terms, numbers or the like. It should be understood, however, that all of these and similar 15 terms are to be associated with the appropriate physical quantities and are merely convenient labels applied to these quantities.

Unless specifically stated otherwise, as apparent from the following discussions, it is appreciated that throughout the specification discussions utilizing terms such as "processing," "computing," "calculating," "determining," or the like, refer to the action 20 and/or processes of a computer or computing system, or similar electronic computing device, that manipulate and/or transform data represented as physical, such as electronic, quantities within the computing system's registers and/or memories into other data similarly represented as physical quantities within the computing system's memories,

registers or other such information storage, transmission or display devices.

Embodiments of the present invention may include apparatuses for performing the operations herein. This apparatus may be specially constructed for the desired purposes, or it may comprise a general purpose computing device selectively activated or
5 reconfigured by a program stored in the device. Such a program may be stored on a storage medium, such as, but is not limited to, any type of disk including floppy disks, optical disks, CD-ROMs, magnetic-optical disks, read-only memories (ROMs), random access memories (RAMs), electrically programmable read-only memories (EPROMs), electrically erasable and programmable read only memories (EEPROMs), magnetic or
10 optical cards, or any other type of media suitable for storing electronic instructions, and capable of being coupled to a system bus for a computing device.

The processes and displays presented herein are not inherently related to any particular computing device or other apparatus. Various general purpose systems may be used with programs in accordance with the teachings herein, or it may prove convenient
15 to construct a more specialized apparatus to perform the desired method. The desired structure for a variety of these systems will appear from the description below. In addition, embodiments of the present invention are not described with reference to any particular programming language. It will be appreciated that a variety of programming languages may be used to implement the teachings of the invention as described herein.

20 In the following description and claims, the terms "coupled" and "connected," along with their derivatives, may be used. It should be understood that these terms are not intended as synonyms for each other. Rather, in particular embodiments, "connected" may be used to indicate that two or more elements are in direct physical or electrical contact with each other.

"Coupled" may also mean that two or more elements are in direct physical or electrical contact. However, "coupled" may also mean that two or more elements are not in direct contact with each other, but yet still co-operate or interact with each other.

It should be understood that the present invention may be used in a variety of applications. Although the present invention is not limited in this respect, the circuit disclosed herein may be used in many apparatuses such as in the transmitters and receivers of a radio system. Radio systems intended to be included within the scope of the present invention include, by way of example only, cellular radiotelephone communication systems, two-way radio communication systems, one-way pagers, two-way pagers, personal communication systems (PCS), personal digital assistants (PDA's) and the like.

Types of cellular radiotelephone communication systems intended to be within the scope of the present invention include, although not limited to, Direct Sequence - Code Division Multiple Access (DS-CDMA) cellular radiotelephone communication systems, Global System for Mobile Communications (GSM) cellular radiotelephone systems, North American Digital Cellular (NADC) cellular radiotelephone systems, Time Division Multiple Access (TDMA) systems, and Extended-TDMA (E-TDMA) cellular radiotelephone systems

Turning to FIG. 1, an embodiment 100 in accordance with the present invention is described. Embodiment 100 may comprise a portable computing or communication device 10 such as a mobile communication device (e.g., cell phone), a two-way radio communication system, a one-way pager, a two-way pager, a personal communication system (PCS), a portable computer, or the like. Although it should be understood that the scope and application of the present invention is in no way limited to these examples.

Portable device 10 may comprise an application platform 20 and a communication

EL034435704US

platform 30 that are coupled together with an interface 50. Although the scope of the present invention is not limited in this respect, application platform 20 may allow a user to execute a variety of application programs such as email, calendaring, address books, etc. Application platform 20 may also execute any application that are commonly executed on a desktop system, such as, for example, word processing, financial programs, etc.

Application platform may comprise a processor 21 such as, for example, a complex instruction set (CISC) processor, a reduced instruction set (RISC) processor, or the like. Processor 21 may be coupled to an Input/Output (I/O) port 25 that may be used to receive or transmit data from a user. For example, I/O port 25 may be a keyboard, keypad, trackball, or the like. I/O port 25 may be used to select which program(s) are to be executed by processor 21 or to provide application platform 20 with data from the user.

I/O port 25 may also be used to provide communication platform 30 with data. For example, a user may provide the phone number that is to be used to initiate a wireless communication. In this particular embodiment, I/O port 25 may be coupled to both application platform 20 and communication platform 30 to reduce the number of input ports, and thus, the form factor for portable device 10. However, in alternative embodiments, application platform 20 and communication platform 30 may have separate I/O ports.

Application platform 20 may also comprise a memory 22, such as SRAM, that may be used to store data or instructions for processor 21. Memory 22 may also comprise non-volatile storage devices such as flash memory, a disk drive or the like. Application platform 20 may also comprise a display device 23 such as a liquid crystal display (LCD) to display information associated with programs being executed on either application platform 20 or communication platform 30.

Communication platform 30 may comprise a receiver/transmitter (RT) unit 32 coupled to an antennae 34. A processor 31 may be used to process the wireless communications received by RT unit 32 or to be transmitted by communication platform 30. Processor 31, may comprise a CISC processor, a RISC processor, a digital signal processor, or any combination thereof. In this particular embodiment, processor 31 may be used to process communications independently from processor 21 of application platform 20. For example, processor 31 may be used to transmit or receive communications even if processor 21 is not in operation or is powered off.

Processor 31 may be coupled to a memory 33 that may comprise, for example, volatile memory, such as SRAM, or non-volatile memory, such as flash. Memory 31 may be used to store communications received by communication platform 30 or to store user profile data (e.g., security or identification data) that may be used to transmit a communication. At least one advantage of this particular embodiment is that memory 33 and memory 22 may be separate from each other and be operated independently. This may be advantageous in that wireless platform 30 may be operated independently from application platform 20 and vice versa. This may also provide power savings since either memory 22 or 33 may be powered off when not in use. It should also be understood that communication platform 30 may comprise other components, such as filters, A/D converters, etc (not shown) that may be used to transmit or receive wireless communications.

Portable device 10 may also comprise an interface 50 to couple application platform 20 and communication platform 30. Interface 50 may comprise, for example, a PCMIA (what does this stand for), a serial bus, or other connections to exchange information when appropriate. For example, interface 50 may allow application platform 20 to initiate a

communication with communication platform 30 or may permit communication platform 30 to provide application platform 20 with data that received with a communication.

In addition, interface 50 may allow application platform 20 and communication platform 30 to operate independently from each other. For example, interface 50 may, among other things, control the flow of data or commands between application platform 20 and communication platform 30. Consequently, interface 50 may isolate, either in whole or part, application platform 20 and communication platform 30 from each other. By controlling the flow of data or commands, interface 50 may reduce the risk that application platform 20 inappropriately transmits a message or interferes with other communication systems by causing communication platform 20 to malfunction. This may be desirable to reduce the risk that a virus on application platform 20 infects or affects communication platform 30. This, in turn, may reduce the risk that communication platform 30 inappropriately affects the communication system with which it is in communication. Likewise, interface 50 may also control or restrict the flow of information that is shared from communication platform 20 to application platform 30.

Interface 50 may also provide a standard or uniform technique for sharing information between application platform 30 and communication platform 20. For example, interface 50 may permit processor 21 and processor 31 to share information (e.g., information stored in memory 22 or 33), or may couple communication platform 30 to I/O port 20 so that a user may provide data or commands to communication platform 30. This may provide the flexibility of writing or executing computer programs (e.g., applications, operating systems, etc) on application platform 20 without having to tailor the computer programs to the particular protocol employed by communication platform 30. Accordingly, interface 50 may permit

applications to be developed for portable device 10 without having to undergo the formal and time consuming type-approval process.

QWRY Referring now to FIG. 2, an example of how interface 50 may be used to isolate an application platform from a communication platform in accordance with an embodiment of the 5 present invention is provided. FIG. 2 is intended to illustrate how various modules or computer programs of an application platform and a wireless platform may be arranged with respect to each other. In this particular example, portable device 10 may comprise a application subsystem 120 that is couple to a wireless subsystem 130 by interface 50. Application subsystem 120 may include an operating system 121 and applications 122 that

10 are executed on processor 21 (see FIG. 1). Although the scope of the present invention is not limited in this respect, operating system may include: Blah blah blah.

Applications 131 may also be executed on processor 21 and include programs intended to process the data provide by a user through an input port (e.g. I/O port 25 of FIG. 1), from wireless subsystem 130, or both. Again, although the invention is not limited in this respect, 15 applications 122 may include blah blah blah.

Wireless subsystem may comprise a communication protocol module 131 that may be used to implement that particular communication standard employed by portable device 10. The communication protocol may be implemented with a real time operating system 132 executing on a processor (e.g., processor 31 of FIG. 1). Wireless subsystem 133 may also 20 comprise a radio 133 that may be implemented in hardware, software, or a combination thereof. As shown, interface 50 provides isolation between application subsystem 120 and wireless subsystem 130 so that applications may be executed on application subsystem 120 regardless of the particular communication protocol 131 implemented by wireless subsystem

130.

Interface 50 also provides for the appropriate and control sharing of data between application subsystem 120 and wireless subsystem 130. For example, interface 50 may permit application platform 120 to initiate or receive a communication using wireless subsystem 130. Interface 50 may also permit a user to provide wireless subsystem 130 with data through an input port (e.g., I/O port 25 of FIG. 1). Consequently, in this particular embodiment, interface 50 may provide sufficient isolation so that applications may be run on application subsystem 120 without interfering with wireless subsystem 130, while at the same time, allowing applications to process the data received through wireless communications. It should be understood that in various embodiments of the present invention, interface 50 may comprise various levels of intelligence or sophistication that provides isolation between application subsystem 120 and wireless subsystem 130. Alternatively, however, interface 50 may not comprise any intelligence and simply be a data path between application subsystem 120 and wireless subsystem 130.

While certain features of the invention have been illustrated and described herein, many modifications, substitutions, changes, and equivalents will now occur to those skilled in the art. For example, application platform 20 and wireless platform 30 may share a common power source, while in alternative embodiments, application platform 20 and wireless platform 30 may have independent power sources that permit processors 21 and 31 to be operated independently. It is, therefore, to be understood that the appended claims are intended to cover all such modifications and changes as fall within the true spirit of the invention.
